

①

MAE

(Mean absolute Error)

$$MAE = \frac{|y_1 - \hat{y}_1| + |y_2 - \hat{y}_2| + \dots + |y_n - \hat{y}_n|}{n}$$

$$MAE = \frac{\sum_{i=1}^n |y_i - \hat{y}_i|}{n}$$

Advan-1* MAE will be in the units of y

Ex - if y represents salary in € (euro)

Then if MAE = 1.5 represents 1.5 euro (€)

2 - Robust to outlier

* Disadvantage

← graph of modulus
is not differentiable
at 0.

(2) MSE (mean squared error)

$$MSE = \frac{1}{n} \sum_{i=1}^n (y_i - \hat{y})^2$$

* what it represent visually

* Adv.

→ can be used as loss function because
it is differentiable

* dis

→ if the unit of y is LPA (Salary) then unit of MSE will be $(LPA)^2$.

→ Hard to interpret

→ not robust to outliers

(3)

RMSE

(Root mean squared error)

$$RMSE = \sqrt{MSE}$$

→ most of the property is same as MSE

* Adv

→ Output will be in same unit as y .

* dis

→ Not so robust in outliers

[More used in deep learning]

④ R² Score

→ it helps to identify how ^{much} one regression line is better than another

→ R² score helps to calculate how much your regression line is better than mean line in this ex.

→ R² score also known as

1. * Coefficient of Determination (R^2)

$$R^2 = \frac{SSR}{SST}$$

SSR ← Sum of Squared Regression
SST ← Sum of Squared Total

$$R^2 = \frac{\sum_i (\hat{y}_i - \bar{y})^2}{\sum_i (y_i - \bar{y})^2}$$

2. Goodness of fit

* formula can be

$$R^2 = 1 - \frac{SSR}{SSM}$$

SSR = Sum of square in reg line

SSM = Sum of square in mean line

$$R^2 = 1 - \frac{\left[\sum_{i=1}^n (y_i - \hat{y}_i)^2 \right]_{\text{reg}}}{\left[\sum_{i=1}^n (y_i - \bar{y})^2 \right]_{\text{mean}}}$$

→ Score will be between 0 and 1

1 for best and 0 for worse

→ it can be Negative also

(if) $\sum_{i=1}^n (y_i - \hat{y}_i)^2 > \sum_{i=1}^n (y_i - \bar{y})^2$

$$\sum_{i=1}^n (y_i - \hat{y}_i)^2 > \sum_{i=1}^n (y_i - \bar{y})^2$$

$$\sum_{i=1}^n (y_i - \hat{y}_i)^2 > \sum_{i=1}^n (y_i - \bar{y})^2$$

(5) Adjusted R^2 Score

* formula

$$R^2_{adj} = 1 - \left[\frac{(1 - R^2)(n - 1)}{(n - 1 - k)} \right]$$

$R^2 \rightarrow R^2$ score

$n \rightarrow$ no. of ~~rows~~ rows

$k \rightarrow$ no. of independent cols in data

$\rightarrow$ Adj R^2 score will help when you have irrelevant column in your data

* Multiple Linear Regression

$$y = mx_1 + mx_2 + b$$

$\downarrow$
- for 3 dimension

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2$$

$\rightarrow$ for n dimension

$$y = \beta_0 + \beta_1 x_1 + \dots + \beta_n x_n \quad \text{or} \quad y = \beta_0 + \sum_{i=1}^n \beta_i x_i$$

* Coefficients (β_1, β_2) are representing weights

$$\begin{bmatrix} (x_1 - \bar{x}_1) & (x_2 - \bar{x}_2) \end{bmatrix} \begin{bmatrix} \beta_1 \\ \beta_2 \end{bmatrix} = (y - \bar{y})$$

Let $X = \begin{bmatrix} x_1 & x_2 \\ \vdots & \vdots \\ x_n & x_n \end{bmatrix}$ be a matrix of size $n \times 2$ and $Y = \begin{bmatrix} y_1 \\ \vdots \\ y_n \end{bmatrix}$ be a column vector of size $n \times 1$.

Then the normal equations for the regression line are given by:

$$X'X\beta = X'Y$$

$$X'X = \begin{bmatrix} n & \sum x_i \\ \sum x_i & \sum x_i^2 \end{bmatrix}$$

$$X'Y = \begin{bmatrix} \sum y_i \\ \sum x_i y_i \end{bmatrix}$$

$$\begin{bmatrix} n & \sum x_i \\ \sum x_i & \sum x_i^2 \end{bmatrix} \begin{bmatrix} \beta_1 \\ \beta_2 \end{bmatrix} = \begin{bmatrix} \sum y_i \\ \sum x_i y_i \end{bmatrix}$$

Let $\bar{x} = \frac{\sum x_i}{n}$ and $\bar{y} = \frac{\sum y_i}{n}$

$$\beta_1 = \frac{\sum (x_i - \bar{x})(y_i - \bar{y})}{\sum (x_i - \bar{x})^2}$$
